# Ward type identities for the 2d Anderson model at weak disorder

Jacques Magnen, Gilles Poirot, Vincent Rivasseau
Centre de Physique Théorique, École Polytechnique

## Abstract

Using the particular momentum conservation laws in dimension $d = 2$, we can rewrite the Anderson model in terms of low momentum long range fields, at the price of introducing electron loops. The corresponding loops satisfy a Ward type identity, hence are much smaller than expected. This fact should be useful for a study of the weak-coupling model in the middle of the spectrum of the free Hamiltonian.

## 1 Introduction

We consider a continuous Anderson model in dimension $d = 2$. The model is defined through the following Hamiltonian

$$H = -\Delta + \lambda V \tag{1}$$

where $V$ is a Gaussian random field which is a regularized white noise.

We are interested in the density of states at weak disorder ($\lambda \ll 1$) and in the free spectrum (at energy $E > 0$). It is well known [1] that because of ergodicity, the density of states is a deterministic quantity given by

$$\rho(E) = \frac{1}{\pi} \lim_{\sigma \to 0} \lim_{\Lambda \to \infty} \mathbb{E} \left[ \mathrm{Im}\, G(E + i\sigma; 0, 0) \right] \tag{2}$$

where $G$ is the resolvent, or Green's function, of the system

$$G(z) = (H - z)^{-1} \tag{3}$$

The limit $\Lambda \to \infty$ stands for the fact that we must work in a finite volume to have well defined quantities and then take the thermodynamic limit.

Thus the problem amounts to studying the mean Green's function. Perturbations suggest that

$$\mathbb{E}\left[G(E+i\sigma)\right] \sim \frac{1}{p^2-E-i\sigma-\Sigma} \tag{4}$$

where the self-energy $\Sigma$ is given at leading order by the Born approximation, [2, 3]

$$\begin{aligned} C &= \frac{1}{p^2-E-i\sigma-\Sigma_{Born}} && (5)\\ \Sigma_{Born} &= \lambda^2\,\mathbb{E}(VCV) && (6) \end{aligned}$$

which yields a finite imaginary part of order $\lambda^2$.

In this paper, we derive a Ward type identity which should allow to control the mean Green's function for *initial* imaginary part of order $\lambda^{2+\varepsilon}$, *i.e.* much smaller than the expected final imaginary part. This is not enough to go to the limit $\sigma \longrightarrow 0$ which is in fact equivalent to $\sigma \simeq \lambda^3$ thanks to spectral averaging techniques [4] or equivalently complex translation of the potential [5]. Nevertheless, we think that this kind of identity should play a role in studying the mean Green's function of the model and in proving its expected long range decay.

We give first a heuristic presentation of this identity which is a little bit complicated. Then we will derive it in a simplified model in a single cube of size $\lambda^{-2-\varepsilon}$. This result, when combined with a polymer expansion of the resolvent would allow to control the thermodynamic limit of the model with $\sigma = \lambda^{2+\varepsilon}$, in the same way than ([5, 6]).

## 2 Phase space picture and matrix model

Our study is based on a phase space multiscale analysis [5, 7, 6]. We divide the momentum space into slices such that in the $j^{th}$ slice $\Sigma_j$, we have $M^{-j-1} \leqslant |p^2-E| \leqslant M^{-j}$ for some integer $M \geqslant 2$. Then the real space is divided into lattices $\mathbb{D}_j$ of cubes of dual size $M^j$.

The point is that the potential $V$ seen as an operator $\mathbf{V}$ has a kernel in momentum space given by

$$\mathbf{V}(p,q) = \hat{V}(p-q). \tag{7}$$

When $p$ and $q$ are restricted to low slices, *i.e.* very close to $p^2 = E$, knowing the momentum transfer $p-q$ allows to recover back the pair $\{p,-q\}$ [8, 9] so that the potential has a very strong matrix flavor [7].

We call $\eta_j$ a smoothed projector on the slice $\Sigma_j$ that we further divide into angular sectors $S^j_\alpha$ of width $M^{-j/2}$, corresponding to some $\eta_{\alpha_j}$. We write $\bar{\alpha}$ for the opposite sector to $\alpha$ and we introduce also the notation

$$\eta_{\bar{j}} = \sum_{k \geqslant j} \eta_k \tag{8}$$

For any operator $A$ we write

$$A^{jk} = \eta_j A \eta_k \tag{9}$$

Finally, for any lattice $\mathbb{D}_j$ of cubes $\Delta$, we can make an orthogonal decomposition of the field $V$ into a sum of fields $V_\Delta$, the support of $V_\Delta$ being on a close neighborhood of $\Delta$ [5]. Then, using the matrix aspect of the potential, we can derive the following estimates [5, 6]

**Lemma 1**

*There are constants $K_1$ and $K_2$ such that for all $j \leqslant k$, $a \geqslant 1$ and $\Delta \in \mathbb{D}_k$*

$$\mathbb{P}\left( \| V_\Delta^{\bar{j}\bar{k}} \| \geqslant a K_1 M^{-j/2} \right) \leqslant K_2 \, e^{-a^2 M^{\frac{k}{2} - \frac{j}{3}}} \tag{10}$$

**Lemma 2** *(Tadpole-free operators)*

*There are constants $K_1$ and $K_2$ such that for all $j \leqslant k$, $a \geqslant 1$ and $\Delta, \Delta' \in \mathbb{D}_k$*

$$\mathbb{P}\left( \| : V_\Delta^{\bar{k}j} C V_{\Delta'}^{j\bar{k}} : \| \geqslant a K_1 M^{-\frac{(k-j)}{2}} \right) \leqslant K_2 \, e^{-a^2 M^{\frac{j}{6}}} \tag{11}$$

*where :: stands for the Wick ordering*

$$: V_\Delta^{\bar{k}j} C V_{\Delta'}^{j\bar{k}} := V_\Delta^{\bar{k}j} C V_{\Delta'}^{j\bar{k}} - \left\langle V_\Delta^{\bar{k}j} C V_{\Delta'}^{j\bar{k}} \right\rangle \tag{12}$$

**Lemma 3** *(Almost diagonal operators)*

*There are constants $K_1$ and $K_2$ such that for all $j \leqslant k$, $0 < r < 1$, $a \geqslant 1$ and $\Delta \in \mathbb{D}_k$*

$$\mathbb{P}\left( \| {}^{(r)}\underline{V}_\Delta^{\bar{j}\bar{k}} \| \geqslant a K_1 M^{-\frac{j}{2}(1+\frac{r}{2})} \right) \leqslant K_2 \, e^{-a^2 M^{\frac{k}{2} - \frac{j}{3} - \frac{rj}{6}}} \tag{13}$$

*where*

$${}^{(r)}V_\Delta^{jk} \equiv \sum_{|\alpha-\beta| \leqslant M^{-rj/2}} \eta_{\alpha_j} V_\Delta \eta_{\beta_k} + \sum_{|\alpha-\bar{\beta}| \leqslant M^{-rj/2}} \eta_{\alpha_j} V_\Delta \eta_{\beta_k} \tag{14}$$

# 3 Result

We are looking at a simplified model in a single cube: in $\mathbb{R}^2/_{\lambda^{-2-\varepsilon}\mathbb{Z}^2}$ we consider the following Hamiltonian

$$H = -\Delta + \lambda V \tag{15}$$

where $V$ is a Gaussian random field with translation invariant covariance $\xi \in \mathcal{C}_0^\infty(\mathbb{R}^2)$ such that $\xi^{1/2} \in \mathcal{C}_0^\infty(\mathbb{R}^2)$ (the square root being taken in operator sense). The result could be extended to $\xi \in \mathcal{S}(\mathbb{R}^2)$ but the development would be much heavier.

We are interested in computing the mean Green's function

$$\bar{G}(E - i\sigma) = \int d\mu(V)\,(H - E - i\sigma)^{-1} \tag{16}$$

for which we have the following result

**Theorem 1** *(Ward type identity)*
*There exists $\nu > 0$ such that for all $\sigma \leqslant \lambda^2$*

$$\|\bar{G}(E) - C\| \leqslant O(1)\left(\frac{\lambda^{2+\nu}}{\sigma}\right)^3 \frac{1}{\sigma} \tag{17}$$

*where $C$ is the renormalized propagator at leading order (Born approximation).*

Moreover, we can iterate the development in order to obtain an asymptotic expansion to all orders.

This result together with a polymer expansion [5] would allow to control the thermodynamic limit for imaginary part

$$\sigma \geqslant \lambda^{2+\varepsilon}. \tag{18}$$

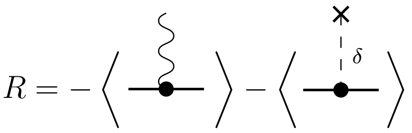
Therefore we can investigate the mean Green's function up to a region with imaginary part much smaller than the expected final one. We cannot for the moment go to the real axis which would require to have $\nu > 1$. Nevertheless, we think that this kind of identity should play a role in the study of the mean Green's function and of the density of states.

# 4 Heuristic presentation

Let us assume that we are working in the region of momenta $|p^2 - E| \leqslant M^{-j_1}$, where

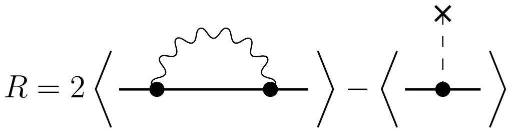
$$\begin{aligned} j_1 &= (1-\nu_1)j_0 & (19)\\ \lambda^2(\log\lambda^{-1})^2 &\simeq M^{-j_0} & (20)\end{aligned}$$

We are looking at the off-diagonal part of the potential, *i.e.* the $V_{\alpha\beta}$'s such that $\alpha$ is quite different from $\beta$ or $\bar{\beta} \equiv \pi + \beta$. We know that in this case, sectors are preserved up to $M^{-j_0/2}$ and even better [6]. If we introduce a counter-term $\delta$ and perform one step of perturbation, *e.g.* by putting an interpolation parameter on the potential and the counter-term, we get a remainder term which looks like



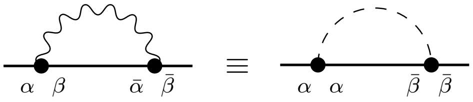
(21)

We can integrate the $V$ by parts and get

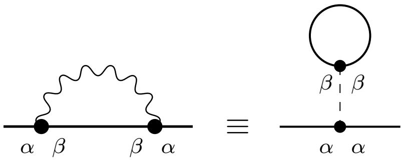


(22)

Sector conservation tells us that there are two possible configurations:



(23)



(24)

We used the fact that $V$ being almost ultra-local we can identify both ends of its propagator (the wavy line) and replace it by the dashed line which corresponds to the low momentum channel. Furthermore, for the first term, we used

$$(\eta_\beta G \eta_{\bar{\alpha}})(x,x) = (\eta_\beta G \eta_{\bar{\alpha}})^{\mathrm{t}}(x,x) = (\eta_\alpha G \eta_{\bar{\beta}})(x,x) \tag{25}$$

where $A^{\mathrm{t}}$ stands for the transposed operator, whose kernel is

$$A^{\mathrm{t}}(x,y) = A(y,x) \tag{26}$$

The first configuration corresponds to the insertion of two fields of very low momentum, *i.e.* to almost diagonal operators, and as such is very small. Thus we just need to see how the second term, which is the insertion of a tadpole, will kill the counter-term, at least at leading order.

First, we can remark that if $\alpha$ and $\beta$ are far enough from each other, the momentum flowing into the loop has a size $M^{-j_1}$, being at the intersection of two tubes of size $M^{-j_0/2} \times M^{-j_1}$. But we can go further: if all the incoming legs at the vertex are in the "very low" slice $\Sigma_{j_0}$, the ingoing momentum has a size $M^{-j_0}$. This means that either we have a very small momentum flowing into the loop or one of the four legs is "high", which means that $|p^2 - E|$ is large. This allows to earn a small factor.

If we set the counter-term equal to the tadpole with the bare propagator $C_0$, we are led to study

$\Gamma_{\alpha\beta}(k) =$  (27)

where the slashed line stands for $G - C_0$. In momentum space the contribution of the loop is

$$\int dp\, \eta_\beta(p)\eta_\beta(p+k)(G - C_0)(p+k,p). \tag{28}$$

The key point is then to notice that when $p$ is close to $k_\beta$, the center of the sector $\beta$ in momentum space, one can write

$$\begin{aligned} 2k.k_\beta + k^2 &= \left[(p+k)^2 - E - i\sigma\right] - \left[p^2 - E - i\sigma\right] - 2k.(p - k_\beta) && (29)\\ &= C_0^{-1}(p+k) - C_0^{-1}(p) + O\left(|k||p - k_\beta|\right) && (30) \end{aligned}$$

Using the resolvent identity

$$G - C_0 = -C_0\lambda V G = -G\lambda V C_0 \tag{31}$$

we get

$(2k.k_\beta + k^2)\Gamma_{\alpha\beta}(k) \simeq$  (32)

where the thick line stands for $\eta_\beta$.

The perturbative reformulation of this identity is the following. Starting from a vertex function

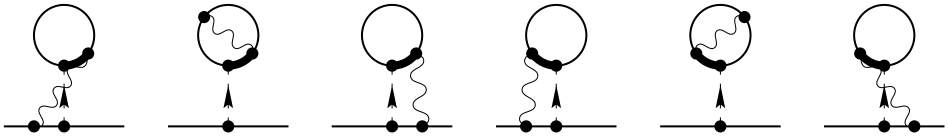
$$\Gamma^{(\beta)}_{2,1}(p,k) = C_\beta(p)C_\beta(p+k) \tag{33}$$

we have the identity

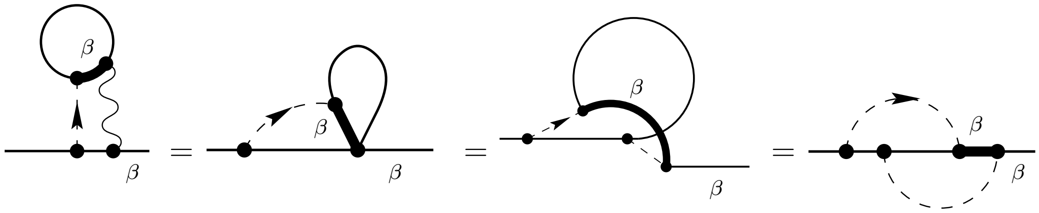
$$(2k.k_\beta + k^2)\Gamma^{(\beta)}_{(2,1)}(p,k) \simeq C_\beta(p) - C_\beta(p+k) \tag{34}$$

This looks very much like a perturbative Ward identity in Quantum Electrodynamics where we express the vertex function $\Gamma_{2,1}$ (between an electron, a positron and a photon) in terms of the difference of two electron propagators.

Once again, we integrate by parts the $V$ which has been taken down. This leads to six possible graphs



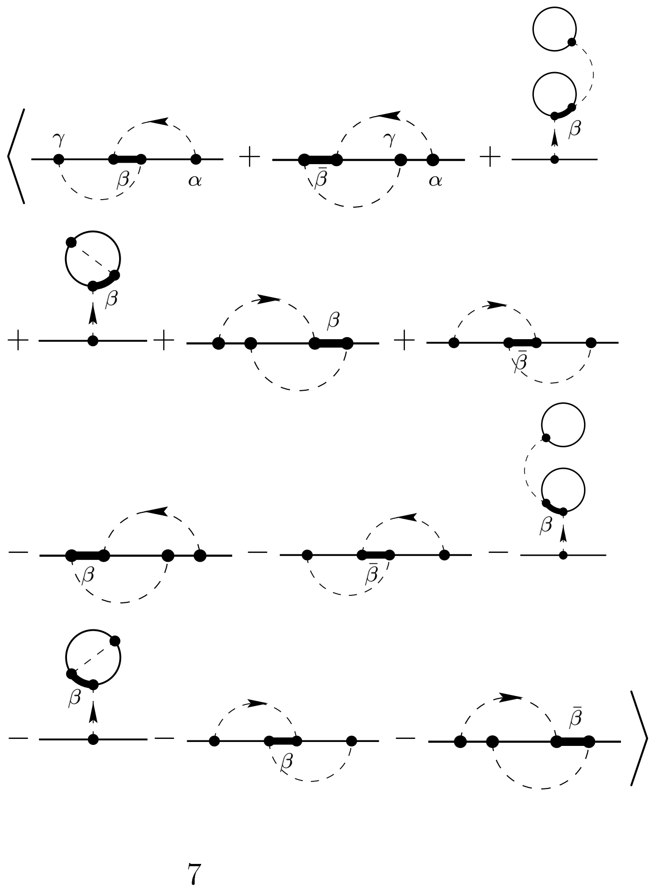
Then we use sector conservation and perform various unfolding operations. In order to illustrate the process, let us show how it works on the following typical term (using the fact that a wavy line is almost a $\delta$ function)



(35)

In the end we obtain 12 terms which are

$$(2k.k_\beta + k^2)\Gamma_{\alpha\beta}(k) \simeq$$



(36)

We have two types of graphs:

- graphs without electron loops, containing very low momentum field insertions,
- and graphs with remaining electron loops.

The graphs in the first category are small. In the second category, the 3rd, 4th, 9th and 10th graphs form two pairs which almost compensate each other ($3-9$ and $4-10$).

The point is that when all the incoming legs at the various vertices are "very low", the momenta flowing into the loops have size $M^{-j_0}$. This implies that the dashed lines stand for *propagators* which decay on a length scale $M^{j_0}$. But $\eta_\beta$ (the thick line) decays on a scale $M^{j_1} \ll M^{j_0}$, therefore it is almost-local with respect to the scale $M^{j_0}$ and we can approximate it by a point. This means that the graphs number 3 and 9 as well as the number 4 and 10 compensate each other, up to a gradient term in $M^{-(j_0-j_1)}$.

This conclude our heuristic description of the reasons for which Theorem 1 holds. The next section is devoted to the proof.

# 5 Proof of Theorem 1

## 5.1 Notations

First of all, we introduce various notations

- We define $_\downarrow \equiv \eta_\downarrow = \eta_{\bar{j}_1}$ et $_\uparrow \equiv \eta_\uparrow = (1-\eta_{\bar{j}_1})$, so that every operator $A$ can be written

$$A = {}_\uparrow A_\uparrow + {}_\uparrow A_\downarrow + {}_\downarrow A_\uparrow + {}_\downarrow A_\downarrow \tag{37}$$

- for $0 < r < 1$ to be fixed later, we define

$$\alpha \sim \beta \Leftrightarrow |\alpha - \beta| \leqslant M^{-r\frac{j_0}{2}} \tag{38}$$

- for $K = O(1)$ we note

$$\alpha \simeq \beta \Leftrightarrow |\alpha - \beta| \leqslant K M^{-j_0/2} \tag{39}$$

- finally we introduce

$$j_2 = (1-\nu_2) j_0 > j_1 \tag{40}$$

## 5.2 Starting the development

We define the counter-term through the self-consistent equation

$$\begin{aligned}\Sigma(x-y) &= \lambda^2\xi(x-y)C(x-y) &(41)\\ C &= \frac{1}{p^2-E-i\sigma-\Sigma} &(42)\end{aligned}$$

Then we set

$$\begin{aligned}G(t) &= \frac{1}{p^2-E-i\sigma-\Sigma+t\lambda V+t^2\Sigma} &(43)\\ \bar{G}(t) &= \mathbb{E}\left[G(t)\right] &(44)\end{aligned}$$

so that we can write

$$\bar{G}=\bar{G}(1)=\bar{G}(0)+\int_0^1 \partial_t\bar{G}(t)\,dt = C+\int_0^1 \partial_t\bar{G}(t)\,dt \tag{45}$$

Then our problem reduces to the study of

$$\begin{aligned}\partial_t\bar{G} &= -\left\langle G(\lambda V+2t\Sigma)G\right\rangle &(46)\\ &= 2t\int dx\,dy\,\left\langle G(.,x)\left[\lambda^2\xi(x,y)G(x,y)-\Sigma(x,y)\right]G(y,.)\right\rangle &(47)\\ &= 2t\int dx\,dy\,\left\langle G(.,x)\left[\lambda^2\xi(x,y)(G-C)(x,y)\right]G(y,.)\right\rangle &(48)\\ &\equiv 2t\left\langle G\left[\lambda^2\xi*(G-C)\right]G\right\rangle &(49)\end{aligned}$$

where we have integrated the $V$ by parts from (46) to (47).

If we plug in the “high” and “low” slices we get

$$\begin{aligned}\partial_t\bar{G} &= \sum_{i_1,\dots,i_4\in\{\downarrow,\uparrow\}} 2t\left\langle G\eta_{i_1}\left[\lambda^2\xi*\eta_{i_2}(G-C)\eta_{i_3}\right]\eta_{i_4}G\right\rangle &(50)\\ &= \sum_{i_1,\dots,i_4\in\{\downarrow,\uparrow\}} \partial_t\bar{G}_{i_1\dots i_4} &(51)\end{aligned}$$

## 5.3 Higher part

We can quite easily deal with the case $(i_1,\dots,i_4)\neq(\downarrow,\dots,\downarrow)$ because we have a high leg.

**Lemma 4**

$$\sum_{(i_1,\dots,i_4)\neq(\downarrow,\dots,\downarrow)} \|\partial_t\bar{G}_{i_1\dots i_4}\| \leqslant O(1)\lambda^{\nu_1}\left(\frac{\lambda^2}{\sigma}\right)^2\times\frac{1}{\sigma} \tag{52}$$

**Proof**

We start with

$$G(t) - C = -C(\lambda V + t^2\Sigma)G(t) \tag{53}$$

then, we write the covariance $\xi$ as the integration of two insertions of an auxiliary field $U$.

$$\partial_t \bar{G}_{i_1 \dots i_4} = -2t \int G\eta_{i_1}(\lambda U)\eta_{i_2} C(\lambda V + t^2\Sigma) G \eta_{i_3}(\lambda U)\eta_{i_4} G \, d\mu(V)\, d\mu(U) \tag{54}$$

At this point we perform a large field versus small field decomposition [5, 6]

$$1 = \varepsilon(U,V) + (1-\varepsilon)(U,V) \tag{55}$$

where $\varepsilon$ is a smooth function which forces

$$\begin{aligned} \|V^{\bar{j}\bar{k}}\| &\leqslant O(1) M^{-\frac{j_1}{2}} M^{\tau_1 \max(\frac{j_1-k}{2},0)} && (56)\\ \|U^{\bar{j}\bar{k}}\| &\leqslant O(1) M^{-\frac{j_1}{2}} M^{\tau_1 \max(\frac{j_1-k}{2},0)} && (57)\\ \|U^{\bar{k}j} C^j V^{j\bar{k}}\| &\leqslant O(1) M^{-(\frac{k-j}{2})} M^{\tau_1 \max[(j_1-j),0]} && (58) \end{aligned}$$

The last condition is possible because $U$ and $V$ cannot contract together, therefore we can use lemma 2 on tadpole-free operators. Thanks to lemmas 1 and 2, we find that the large field contribution will be small, of order

$$\mathbb{E}\left[\|\partial_t G_{i_1\dots i_4}\|(1-\varepsilon)\right] \leqslant O(1)\, \lambda^{-2}\, e^{-\kappa \lambda^{-2\tau_1(1-\nu_1)}} \times \frac{1}{\sigma^3}, \tag{59}$$

for some constant $\kappa$.

In the small field region, we will use the fact that we have a high leg so that in some sense we can make perturbations. Suppose that $\eta_{i_4}$ is the high leg at scale $k_0$, the operator $\lambda U^{i_3 i_4}$ will have a size $\lambda M^{-k_0/2} \gg \lambda^2$. But if we perform a resolvent expansion on $\lambda U^{i_3 i_4} G$ we will get $\lambda U^{i_3 i_4} C^{k_0} \lambda V G$ thus we earn an extra factor $\lambda U^{i_3 i_4} C^{k_0}$ whose norm is $\lambda M^{k_0/2} \ll 1$. Then we can iterate the process until either we fall back to a scale of order $j_0$ or we have earned enough small factors.

**Lemma 5** *(stairway expansion)*

$$\begin{aligned} (1-\eta_{\bar{m}})G &= \sum_{k_0<m} C^{k_0}\left[1 - (t^2\Sigma + \lambda V \eta_{\bar{j}_0})G\right] \\ &\quad - \sum_{\substack{k_0<m \\ k_1<j_0}} C^{k_0}\lambda V C^{k_1}\left[1 - (t^2\Sigma + \lambda V \eta_{\bar{k}_1})G\right] \\ &\quad + \sum_{\substack{k_0<m \\ 0<k_1<j_0 \\ k_2<k_1}} C^{k_0}\lambda V C^{k_1}\lambda V C^{k_2}\left[1 - (t^2\Sigma + \lambda V \eta_{\bar{k}_2})G\right] - \dots \end{aligned} \tag{60}$$

*where $C^k = \eta_k C$ and $\eta_{\bar{0}} = 1$.*

*Of course, we have a similar result for $G(1-\eta_{\bar{m}})$ by expanding to the left.*

**Proof**

The proof is by induction on $m$ thanks to the resolvent identity

$$G = C - C(t^2\Sigma + \lambda V)G \tag{61}$$

that we write as

$$\eta_p G = C^p \left[1 - C(t^2\Sigma + \lambda V \eta_{\bar p})G\right] - \sum_{q<p} C^p \lambda V \eta_q G \tag{62}$$

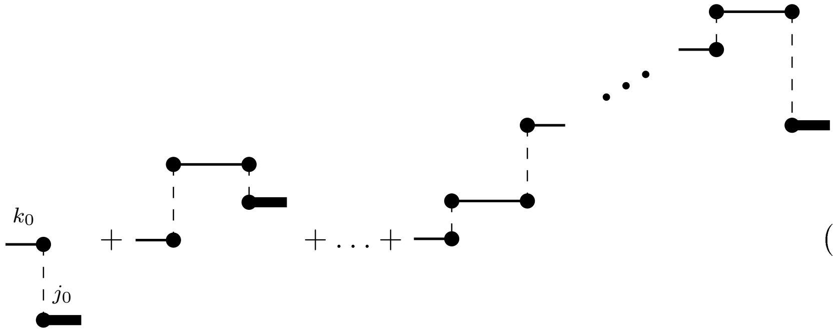
■

In equation (60) we can group the various terms according to whether they end by a $C$, a $\Sigma G$ or a $VG$. Then we can introduce a diagrammatic representation

$$(1 - \eta_{\bar j_0})G \quad =$$

$$= A_V + A_\Sigma + A_C \tag{63}$$

$$A_V \quad =$$



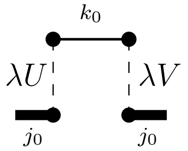
(64)

$A_\Sigma$ and $A_C$ can be represented in the same way by changing the rightmost term.

We apply the stairway expansion on each leg which has its momentum above the scale $j_0$ and is not linked to a long enough stairway. This allows to show that each field insertion behaves like $O(1)\lambda^2$. Furthermore, we earn a factor $\lambda M^{j_1/2} M^{\tau_1 j_1/2} \sim \lambda^{\nu_1 - \tau_1}$, thanks to the $\lambda U$ which have a high leg. Indeed, the corresponding insertion of $\lambda U$ will transform into the insertion of a sum of stairways. The $A_V$ part has the following form:

- the second order insertion is

$$A_2 \equiv \sum_{k_0<j_1}$$



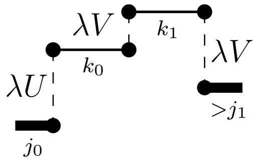
(65)

Since $U$ and $V$ cannot contract together, the small field condition tells us that

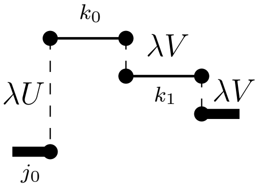
$$\|A_2\| \leqslant O(1) \sum_{k_0<j_1} \lambda^2 M^{-(\frac{j_0-k_0}{2})} \leqslant O(1)\lambda^2 M^{-(\frac{j_0-j_1}{2})} \tag{66}$$

- at third order, we have two possible configurations

$$A_3^{(1)} \equiv \sum_{\substack{k_0<j_1 \\ k_1\leqslant k_0}}$$



and $A_3^{(2)} \equiv \sum_{\substack{k_0<j_1 \\ k_1>k_0}}$



(67)

For $A_3^{(1)}$, one finds

$$\begin{aligned}
\|A_3^{(1)}\| &\lesssim \lambda M^{-k_0/2} M^{k_0} \lambda M^{-k_1/2} M^{\tau_1(\frac{j_1-k_0}{2})} M^{k_1} \lambda M^{-k_1/2} && (68)\\
&\lesssim \lambda^2 \left(\lambda M^{j_1/2}\right) M^{-(1-\tau_1)(\frac{j_1-k_0}{2})} && (69)\\
&\lesssim \lambda^2 \left(\lambda M^{j_1/2}\right) && (70)
\end{aligned}$$

In the same way, one finds for $A_3^{(2)}$

$$\begin{aligned}
\|A_3^{(2)}\| &\lesssim \lambda^2 M^{-(\frac{k_1-k_0}{2})} M^{\tau_1(j_1-k_0)} M^{k_1} \lambda M^{-k_1/2} M^{\tau_1(\frac{j_1-k_1}{2})} && (71)\\
&\lesssim \lambda^2 \left(\lambda M^{j_1/2}\right) M^{-(1-3\tau_1)(\frac{j_1-k_0}{2})} && (72)\\
&\lesssim \lambda^2 \left(\lambda M^{j_1/2}\right) && (73)
\end{aligned}$$

- fourth and higher order terms can be treated similarly. We find the same power counting with more and more small factors as the order increases.

We do the same to bound the $A_C$ and $A_\Sigma$ parts and get the announced result

$$\|\partial_t \bar{G}_{i_1\ldots i_4}\| \leqslant O(1)\lambda^{\nu_1} \left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \tag{74}$$

■

## 5.4 Lower part

We introduce the angular sectors

$$\partial_t \bar{G}_\downarrow \equiv \partial_t \bar{G}_{\downarrow\ldots\downarrow} = 2t \sum_{\alpha_1\ldots\alpha_4} \left\langle G\eta_{\alpha_1} \left[\lambda^2 \xi * \eta_{\alpha_2}(G-C)\eta_{\alpha_3}\right] \eta_{\alpha_4} G\right\rangle \tag{75}$$

First we extract the *degenerate* part of the sum over the sectors, *i.e.* the part $(\alpha_1 \sim \alpha_2, \bar{\alpha}_2)$. In order to do so, we define the almost diagonal part of ${}_\downarrow U_\downarrow$ (with momentum close to 0 or $2\sqrt{E}$).

$${}_\downarrow U_{\mathrm{diag}\downarrow} = \sum_{\alpha\sim\beta,\bar{\beta}} \eta_\alpha U \eta_\beta \tag{76}$$

Then we write

$$\begin{aligned}
\partial_t \bar{G}_{\downarrow} &= \partial_t \bar{G}_{\downarrow}^{(0)} + \partial_t \bar{G}_{\downarrow}^{(1)} && (77) \\
\partial_t \bar{G}_{\downarrow}^{(0)} &= 2t \int G_{\downarrow} \lambda U_{\mathrm{diag}\downarrow} (G-C)_{\downarrow} \lambda U_{\downarrow} G \, d\mu(U)\, d\mu(V) && (78)
\end{aligned}$$

Keeping only the almost diagonal part for one of the $\lambda U$ allows us to earn a factor $M^{-rj_0/4} = \lambda^{r/2}$ in the small field region, thanks to lemma 3. Therefore, we can treat $\partial_t \bar{G}_{\downarrow}^{(0)}$ in the same way we controlled the higher part and get the following bound.

$$\|\partial_t \bar{G}_{\downarrow}^{(0)}\| \leqslant O(1) \lambda^{r/2} \left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \tag{79}$$

We are left with

$$\begin{aligned}
\partial_t \bar{G}_{\downarrow}^{(1)} &= 2t\lambda^2 \sum_{\substack{\alpha_1 \not\simeq \alpha_2, \bar{\alpha}_2 \\ \alpha_3, \alpha_4}} \int dx\, dy\, \xi(x,y) \\
&\qquad \langle G \eta_{\alpha_1}(.,x) \eta_{\alpha_2}(x,.) (G-C) \eta_{\alpha_3}(.,y) \eta_{\alpha_4}(y,.) G \rangle && (80) \\
&= 2t\lambda^2 \sum_{\substack{\alpha_1 \not\simeq \alpha_2, \bar{\alpha}_2 \\ \alpha_3, \alpha_4}} \int du\, \xi(u) \int dz \\
&\quad \langle G \eta_{\alpha_1}(.,z) \eta_{\alpha_2}(z,.) (G-C) \eta_{\alpha_3}(.,z+u) \eta_{\alpha_4}(z+u,.) G \rangle && (81)
\end{aligned}$$

In the following, we will note

$$\eta_{\gamma}^{(u)}(x,y) = \eta_{\gamma}(x-y+u) = \eta_{\gamma}(x+u,y) = \eta_{\gamma}(x,y-u) \tag{82}$$

## 5.5 Sector conservation and unfolding

If we look at the vertex in momentum space, we have a factor

$$\hat{\eta}_{\alpha_1}(p_1) \hat{\eta}_{\alpha_2}(p_2) \hat{\eta}_{\alpha_3}(p_3) \hat{\eta}_{\alpha_4}(p_4) \delta(p_1 - p_2 + p_3 - p_4) \tag{83}$$

This leads to one of the following possibilities (recall that we defined $\simeq$ in equation 39):

$$\left\{ \begin{array}{c} \alpha_1 \simeq \alpha_4 \text{ and } \alpha_2 \simeq \alpha_3 \\ \text{or} \\ \alpha_1 \simeq \bar{\alpha}_3 \text{ and } \alpha_2 \simeq \bar{\alpha}_3 \end{array} \right. \tag{84}$$

Thus

$$\begin{aligned}
\partial_t \bar{G}^{(1)}_{\downarrow} &= 2t(I_0 + J_0) && (85)\\
I_0 &= \lambda^2 \sum_{\alpha\not\simeq\beta,\bar\beta} \sum_{\substack{\alpha'\simeq\alpha\\ \beta'\simeq\beta}} \int \xi(u)\,du \int dz \left\langle G\eta_\alpha\eta_\beta(G-C)\eta^{(-u)}_{\bar\alpha'}\eta^{(u)}_{\bar\beta'}G\right\rangle && (86)\\
J_0 &= \lambda^2 \sum_{\alpha\not\simeq\beta,\bar\beta} \sum_{\substack{\alpha'\simeq\alpha\\ \beta'\simeq\beta}} \int \xi(u)\,du \int dz \left\langle G\eta_\alpha\eta_\beta(G-C)\eta^{(-u)}_{\beta'}\eta^{(u)}_{\alpha'}G\right\rangle && (87)
\end{aligned}$$

Now we can unfold the $\alpha\beta\bar{\alpha}'\bar{\beta}'$ term, *cf.* equations (23), (25).

$$I_0 = \lambda^2 \sum_{\alpha\not\simeq\beta,\bar\beta} \sum_{\substack{\alpha'\simeq\alpha\\ \beta'\simeq\beta}} \int \xi(u)\,du \int dz \left\langle G\eta_\alpha\eta^{(u)}_{\alpha'}(G-C)\eta_{\bar\beta}\eta^{(u)}_{\bar\beta'}G\right\rangle \tag{88}$$

In order to decouple the $\alpha\alpha'$ and $\beta\beta'$ operators, we insert

$$1 = \int \delta(z-z')\,dz' = \int dk\,dz' e^{ik(z-z')} \tag{89}$$

Let us note $e^{ik\cdot}$ the operator whose kernel is

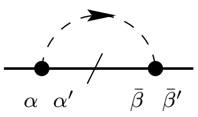
$$\left(e^{ik\cdot}\right)(x,y) = e^{ikx}\delta(x-y) \tag{90}$$

with this notation, we have

$$\begin{aligned}
I_0 &= \lambda^2 \sum_{\alpha\not\simeq\beta,\bar\beta} \sum_{\substack{\alpha'\simeq\alpha\\ \beta'\simeq\beta}} \int \xi(u)\,du \int dk \\
&\quad \left\langle G\eta_\alpha e^{ik\cdot}\eta^{(u)}_{\alpha'}(G-C)\eta_{\bar\beta}e^{-ik\cdot}\eta^{(u)}_{\bar\beta'}G\right\rangle && (91)\\
J_0 &= \lambda^2 \sum_{\alpha\not\simeq\beta,\bar\beta} \sum_{\substack{\alpha'\simeq\alpha\\ \beta'\simeq\beta}} \int \xi(u)\,du \int dk \\
&\quad \left\langle \mathrm{tr}\left[\eta_\beta(G-C)\eta^{(-u)}_{\beta'}e^{-ik\cdot}\right] \times G\eta_\alpha e^{ik\cdot}\eta^{(u)}_{\alpha'}G\right\rangle && (92)
\end{aligned}$$

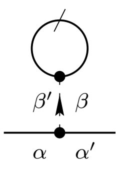
We can adopt the following diagrammatic representation

$I_0 \;=$



(93)

$J_0 \;=$



(94)

Let us write explicitly the various incoming momenta at the half-vertices

$$\begin{aligned} I_0 &= \lambda^2 \sum_{\alpha \not\sim \beta, \bar\beta} \sum_{\substack{\alpha' \simeq \alpha \\ \beta' \simeq \beta}} \int \xi(u)\, du \int d\mu(V) \int dk \int dw_1 \ldots dw_4\, dp_1 \ldots dp_4 \\ & \quad G(., w_1) e^{ip_1 w_1} \hat\eta_\alpha(p_1) \hat\eta_{\alpha'}(p_2) \delta(k - p_1 + p_2) e^{ip_2(u-w_2)} (G-C)(w_2, w_3) \\ & \quad e^{ip_3 w_3} \hat\eta_{\bar\beta}(p_3) \hat\eta_{\bar\beta'}(p_4) \delta(p_4 - p_3 - k) e^{ip_4(u-w_4)} G(w_4, .) \end{aligned} \tag{95}$$

We can see on equation (95) that $k$ allows to go from the sector $\bar\beta$ to the neighboring sector $\bar\beta'$. This implies that $k$ is restricted to a small effective domain around the origin which is a tube $\zeta_\beta$ whose axis is orthogonal to $\beta$ and of size $O(1)M^{-j_1} \times O(1)M^{-j_0/2}$. In the same way, $k$ goes from $\alpha$ to $\alpha'$, thus it must be in the intersection of both tubes $\zeta_\alpha$ and $\zeta_\beta$. Since the angle between those tubes is at least $M^{-rj_0/2}$, $k$ has a norm which is at most $O(1)M^{rj_0/2}M^{-j_1}$.

Thus, we can freely insert a factor $\zeta_0(k)$ which restricts the integration on $k$ to the ball of radius $O(1)M^{rj_0/2}M^{-j_1}$. Of course, the same analysis applies to $J_0$.

$$\begin{aligned} I_0 &= \lambda^2 \sum_{\alpha \not\sim \beta, \bar\beta} \sum_{\substack{\alpha' \simeq \alpha \\ \beta' \simeq \beta}} \int \xi(u)\, du \int \zeta_0(k)\, dk \\ & \quad \left\langle G \eta_\alpha e^{ik\cdot} \eta^{(u)}_{\alpha'} (G-C) \eta_{\bar\beta} e^{-ik\cdot} \eta^{(u)}_{\bar\beta'} G \right\rangle \end{aligned} \tag{96}$$

$$\begin{aligned} J_0 &= \lambda^2 \sum_{\alpha \not\sim \beta, \bar\beta} \sum_{\substack{\alpha' \simeq \alpha \\ \beta' \simeq \beta}} \int \xi(u)\, du \int \zeta_0(k)\, dk \\ & \quad \left\langle \operatorname{tr} \left[ \eta_\beta (G-C) \eta^{(-u)}_{\beta'} e^{-ik\cdot} \right] G \eta_\alpha e^{ik\cdot} \eta^{(u)}_{\alpha'} G \right\rangle \end{aligned} \tag{97}$$

The point is that momentum conservation can be used in a much more efficient way. If we suppose, in equation (95), that the momenta $p_1, \ldots, p_4$ are in the very low slice $\bar\Sigma_{j_2}$, then $k$ will be at the intersection of two tubes of width $M^{-j_2}$ and thus of norm less than $O(1)M^{rj_0/2}M^{-j_2}$.

We can introduce

$$\zeta_0 = \zeta_1 + \zeta_0(1 - \zeta_1) = \zeta_1 + (\zeta_0 - \zeta_1) \tag{98}$$

where $\zeta_1$ forces $|k| \leqslant O(1)M^{rj_0/2}M^{-j_2}$. This will give two terms for $I_0$ (and $J_0$):

- a term $I_1$ (or $J_1$) with $\zeta_1$ having a very small transfer momentum $k$
- a term $I_2$ (or $J_2$) with $\zeta_0(1 - \zeta_1)$ which *must* have a leg above the scale $j_2$.

$$\begin{aligned} I_0 &= I_1 + I_2 & (99) \\ I_1 &= \lambda^2 \sum_{\alpha \not\sim \beta, \bar{\beta}} \sum_{\substack{\alpha' \simeq \alpha \\ \beta' \simeq \beta}} \int \xi(u)\, du \int \zeta_1(k)\, dk \\ &\quad \left\langle G \eta_\alpha e^{ik\cdot} \eta^{(u)}_{\alpha'} (G - C) \eta_{\bar{\beta}} e^{-ik\cdot} \eta^{(u)}_{\bar{\beta}'} G \right\rangle & (100) \end{aligned}$$

Let $\eta_\alpha = \eta_{\alpha\uparrow\downarrow} + \eta_{\alpha\downarrow\downarrow}$, with $\eta_{\alpha\uparrow\downarrow}$ having its support above the scale $j_2$.

$$\begin{aligned} I_2 &= \lambda^2 \sum_{(i_1,\dots,i_4) \neq (\downarrow\downarrow,\dots,\downarrow\downarrow)} \sum_{\alpha \not\sim \beta, \bar{\beta}} \sum_{\substack{\alpha' \simeq \alpha \\ \beta' \simeq \beta}} \int \xi(u)\, du \int (\zeta_0 - \zeta_1)(k)\, dk \\ &\quad \left\langle G \eta_{\alpha i_1} e^{ik\cdot} \eta^{(u)}_{\alpha' i_2} (G - C) \eta_{\bar{\beta} i_3} e^{-ik\cdot} \eta^{(u)}_{\bar{\beta}' i_4} G \right\rangle & (101) \end{aligned}$$

In the following, we will forget the indices $i_1, \dots, i_4$ for shortness.

The terms $I_2$ and $J_2$ have a high leg, so we treat them by an analogue of lemma 4.

**Lemma 6**

$$\|I_2\|, \|J_2\| \leqslant O(1)(\log \lambda^{-1}) \lambda^{\nu_2} \left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \qquad (102)$$

**Proof**

Again, we write the covariance as two insertions of an auxiliary field. Thanks to sector conservation, we have

$$\begin{aligned} I_2 &= \sum_{|\theta| \leqslant K M^{-j_0/2}} I_3(\theta) & (103) \\ I_3(\theta) &= \lambda^2 \sum_{\alpha \not\sim \beta, \bar{\beta}} \sum_{\gamma\delta} \int \xi(u)\, du \int dw \left[\hat{\zeta}_0(w) - \hat{\zeta}_1(w)\right] \\ &\quad \left\langle G \eta_\alpha \eta^{(w)}_\beta (G - C) \eta^{(-u)}_{(\bar{\gamma}+\theta)} \eta^{(w+u)}_{\bar{\delta}} G \right\rangle \delta_{\alpha\gamma} & (104) \end{aligned}$$

Then we write

$$\delta_{\alpha\gamma} = \langle \omega_\alpha \omega_\gamma \rangle_{d\mu_\delta(\boldsymbol{\omega})}, \qquad (105)$$

introducing a Gaussian random vector $\boldsymbol{\omega}$.

$$\begin{aligned} I_3(\theta) &= \lambda^2 \int \left[\hat{\zeta}_0(w) - \hat{\zeta}_1(w)\right] dw \int d\mu(V)\, d\mu(U)\, d\mu_\delta(\boldsymbol{\omega}) \\ &\quad G \left( \sum_{\alpha \not\sim \beta} \eta_\alpha \omega_\alpha U \eta^{(w)}_\beta \right) (G - C) \left( \sum_{\gamma\delta} \eta_\gamma \omega_{\bar{\gamma}-\theta} U \eta^{(w)}_\delta \right) G & (106) \end{aligned}$$

Now, we can perform a large field - small field decomposition and stairway expansions in the small field region. The leading order term corresponds to the insertion of $\lambda(\boldsymbol{\omega} * U^{j_0 j_0})$ and $\lambda^2(\boldsymbol{\omega} * U^{j_0 j_2})C^{j_2}V^{j_2 j_0}$. This gives a factor

$$O(1)\sup|\omega_\alpha|^2 \times \lambda^2 \times \lambda^2 M^{-\frac{(j_0-j_2)}{2}} \tag{107}$$

Therefore, we need to control $\langle \sup|\omega_\alpha|^2\rangle_{d\mu_\delta(\boldsymbol{\omega})}$ in order to conclude. This is done with the following lemma.

**Lemma 7** *Let $\boldsymbol{\omega} \in \mathbb{R}^N$ be a centered Gaussian random vector with covariance*

$$\langle \omega_\alpha \omega_\beta \rangle_{d\mu_\delta(\boldsymbol{\omega})} = \delta_{\alpha\beta} \tag{108}$$

*There exists a constant $C_0$ such that for all $N \geqslant 2$*

$$\left\langle \sup_\alpha |\omega_\alpha|^2 \right\rangle_{d\mu_\delta(\boldsymbol{\omega})} \leqslant C_0 \log N \tag{109}$$

**Proof**

Using Hölder's inequality

$$\begin{aligned}
\left\langle \sup_\alpha |\omega_\alpha|^2 \right\rangle_{d\mu_\delta(\boldsymbol{\omega})} &\leqslant \left\langle (\sup_\alpha |\omega_\alpha|)^{2p} \right\rangle_{d\mu_\delta(\boldsymbol{\omega})}^{1/p} \langle 1^q \rangle_{d\mu_\delta(\boldsymbol{\omega})}^{1/q} && (110)\\
&\leqslant \left\langle \sum_{\alpha=1}^{N} |\omega_\alpha|^{2p} \right\rangle_{d\mu_\delta(\boldsymbol{\omega})}^{1/p} && (111)\\
&\leqslant N^{1/p}\left[(2p-1)!!\right]^{1/p} \leqslant 2N^{1/p}(p!)^{1/p} && (112)
\end{aligned}$$

Then we take $p = [\log N]$. ■

Thus introducing the vector $\boldsymbol{\omega}$ costs only $\log \lambda^{-1}$. Then $J_2$ can be treated in the same way, completing the proof. ■

We return now to the bound on $I_1$ and $J_1$

**Lemma 8**

$$\|I_1\| \leqslant O(1)(\log \lambda^{-1})\lambda^{1-r-4\nu_2}\left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \tag{113}$$

**Proof**

Again we have to get rid of the constraint between $\alpha$ and $\beta$. We write

$$\begin{aligned}
\sum_{\alpha \not\sim \beta} f_{\alpha,\beta} &= \sum_{\alpha\beta} f_{\alpha,\beta} - \sum_{\alpha\sim\beta}(f_{\alpha,\beta} + f_{\alpha,\bar\beta}) && (114)\\
&= \sum_{\alpha\beta} f_{\alpha,\beta} - \sum_{|\theta|<M^{-rj_0/2}} \sum_{\alpha\beta}(f_{\alpha,\beta+\theta} + f_{\alpha,\bar\beta+\theta})\delta_{\alpha\beta} && (115)\\
&= \sum_{\alpha\beta} f_{\alpha\beta} - \sum_{|\theta|<M^{-rj_0/2}} \sum_{\alpha\beta} \left\langle \omega_\alpha\omega_\beta f_{\alpha,\beta+\theta} + \omega_\alpha\omega_\beta f_{\alpha,\bar\beta+\theta} \right\rangle_{d\mu_\delta(\boldsymbol{\omega})} && (116)
\end{aligned}$$

Putting into the expression of $I_1$, we get

$$\begin{aligned}
I_1 &= I_4 + \sum_{|\theta|<M^{-rj_0/2}} \left[ I_5(\theta) + \bar{I}_5(\theta) \right] && (117) \\
I_4 &= \lambda^2 \int \xi(u)\, du \int \zeta_1(k)\, dk \int d\mu(V) \\
&\quad G \Big[ \sum_{\substack{\alpha \\ \alpha' \simeq \alpha}} \eta_\alpha\, e^{ik\cdot} \eta^{(u)}_{\alpha'} \Big] (G - C) \Big[ \sum_{\substack{\beta \\ \beta' \simeq \beta}} \eta_{\bar{\beta}}\, e^{-ik\cdot} \eta^{(u)}_{\bar{\beta}'} \Big] G && (118) \\
I_5(\theta) &= \lambda^2 \int \xi(u)\, du \int \zeta_1(k)\, dk \int d\mu(V)\, d\mu_\delta(\boldsymbol{\omega}) \\
&\quad G \Big[ \sum_{\substack{\alpha \\ \alpha' \simeq \alpha}} \omega_\alpha \eta_\alpha\, e^{ik\cdot} \eta^{(u)}_{\alpha'} \Big] (G - C) \Big[ \sum_{\substack{\beta \\ \beta' \simeq \beta}} \omega_\beta \eta_{\beta+\theta}\, e^{-ik\cdot} \eta^{(u)}_{\beta'+\theta} \Big] G && (119)
\end{aligned}$$

$\bar{I}_5$ is obtained by changing $\beta$ and $\beta'$ into $\bar{\beta}$ and $\bar{\beta}'$ in the expression $I_5$.

We get small factors from the coupling constants $\lambda^2$ and the integration volume for $k$ which is $M^{rj_0} M^{-2j_2}$. On the other hand, we must pay for the resolvents and an extra $M^{(1-r)j_0/2} \sup |\omega_\alpha|^2$ for $I_5 = \sum I_5(\theta)$. Hence

$$\begin{aligned}
\|I_4\| &\leqslant O(1) \lambda^{2-2r-4\nu_2} \left( \frac{\lambda^2}{\sigma} \right)^2 \times \frac{1}{\sigma} && (120) \\
\|I_5\| &\leqslant O(1) (\log \lambda^{-1}) \lambda^{1-r-4\nu_2} \left( \frac{\lambda^2}{\sigma} \right)^2 \times \frac{1}{\sigma} && (121)
\end{aligned}$$

■

Now, we are left with $J_1$ on which we want to apply our Ward-type identity. But we need $k.k_{\beta'}$ to be large enough. We define

$$\zeta_1(k) = \theta_{\beta'}(k) + \varepsilon_{\beta'}(k), \qquad (122)$$

where $\theta_{\beta'}$ restricts the integration on $k$ to the region $k.k_{\beta'} \geqslant \lambda^{2+\nu_3}$. This leads to

$$\begin{aligned}
J_1 &= J_4 + J_5 && (123) \\
J_4 &= \lambda^2 \sum_{\alpha \not\simeq \beta} \sum_{\substack{\alpha \simeq \alpha' \\ \beta' \simeq \beta}} \int \xi(u)\, du \int \varepsilon_{\beta'}(k) J_{\substack{\alpha\alpha' \\ \beta\beta'}}(k)\, dk && (124) \\
J_{\substack{\alpha\alpha' \\ \beta\beta'}}(k) &= \left\langle \mathrm{tr} \left[ \eta_\beta (G - C) \eta^{(-u)}_{\beta'} e^{-ik.} \right] G \eta_\alpha e^{ik\cdot} \eta^{(u)}_{\alpha'} G \right\rangle && (125)
\end{aligned}$$

**Lemma 9**

$$\|J_4\| \leqslant O(1) \lambda^{\nu_3 - \varepsilon} \left( \frac{\lambda^2}{\sigma} \right)^2 \times \frac{1}{\sigma} \qquad (126)$$

**Proof**

Let us write $J_4$ under the following form

$$\begin{aligned} J_4 &= \sum_{\beta,\beta'\simeq\beta} \int \xi(u)\,du \int d\mu(V) \\ &\quad G\left[\lambda^2 \int dz\, \eta_\alpha(.,z) T^{(u)}_{\beta\beta'}(z) \eta_{\alpha'}(z,.)\right] G \qquad (127) \\ T^{(u)}_{\beta\beta'}(z) &= \int \hat{\varepsilon}_{\beta'}(z-z')dz' \left(\eta^{(z')}_{\beta}, (G-C)\eta^{(-z'-u)}_{\beta'}\right) \qquad (128) \end{aligned}$$

$\eta^{(z')}_{\beta}$ and $\eta^{(-z'-u)}_{\beta'}$ are now to be considered as functions and no longer as operators. A stairway expansion on $(G-C)$, in the small field region, proves that the leading contribution is obtained by restricting $\eta_\beta$ and $\eta_{\beta'}$ to the very low slice $j_0$. This yields

$$\begin{aligned} \|T^{(u)}_{\beta\beta'}\|_\infty &\leqslant O(1)\|\eta_{\beta_{j_0}}\|_2^2\, \|G-C\| \int |\hat{\varepsilon}_{\beta'}(x)|\,dx \qquad (129) \\ &\leqslant M^{-j_0/2}\left(\frac{\lambda^2}{\sigma}\right)\lambda^{\nu_3-\varepsilon} \qquad (130) \end{aligned}$$

In order to get (130), we used the fact that our model is restricted to a single cube so that the integration in the direction $k_{\beta'}$ is on a domain of size $\lambda^{-2-\varepsilon}$ instead of the decaying scale $\lambda^{-2-\nu_3}$ of $\hat{\varepsilon}_{\beta'}$. The desired bound follows easily. ■

The previous lemma would extend when we study the thermodynamic limit. In that case, when we work in a given cube $\Delta$, $V$ is replaced by the corresponding $V_\Delta$ whose covariance is

$$\xi_\Delta = \xi^{1/2}\chi_\Delta\xi^{1/2} \qquad (131)$$

The set of all $\chi_\Delta$ is a partition of unity and each $\chi_\Delta$ is a smooth function with compact support around the corresponding cube $\Delta$ [5]. Then we can introduce, $\chi_{\bar{\Delta}}$ smooth with compact support around the support $\bar{\Delta}$ of $\chi_\Delta$ and equal to 1 for all points whose distance to $\bar{\Delta}$ is less than $\lambda^{-2-\varepsilon}$.

Lemma 9 can be extended provided we put further localization functions at the very beginning of the expansion. In the expression of $\partial\bar{G}_\downarrow$, equation (75), we can replace the vertex function

$$\Gamma_\Delta(u_1,\ldots u_4) = \int \xi_\Delta(x,y)\,dx\,dy\,\eta_\downarrow(u_1,x)\eta_\downarrow(x,u_2)\eta_\downarrow(u_3,y)\eta_\downarrow(y,u_4) \qquad (132)$$

by the following one

$$\begin{aligned} \tilde{\Gamma}_\Delta(u_1,\ldots u_4) &= \int \xi_\Delta(x,y)\,dx\,dy\,(\chi_{\bar{\Delta}}\eta_\downarrow)(u_1,x)(\eta_\downarrow\chi_{\bar{\Delta}})(x,u_2) \\ &\qquad (\chi_{\bar{\Delta}}\eta_\downarrow)(u_3,y)(\eta_\downarrow\chi_{\bar{\Delta}})(y,u_4) \qquad (133) \end{aligned}$$

The error term is very small because of the fast decay of $\eta_\downarrow$ on a scale $M^{j_1} \ll \lambda^{-2-\varepsilon}$ and the functions $\chi_{\bar{\Delta}}$ force the tadpole to stay in a cube close to $\Delta$.

### 5.6 Ward term

Finally, we must deal with

$$J_5 = \lambda^2 \sum_{\alpha \not\simeq \beta} \sum_{\substack{\alpha \simeq \alpha' \\ \beta' \simeq \beta}} \int \xi(u)\, du \int \theta_{\beta'}(k) J_{\substack{\alpha\alpha' \\ \beta\beta'}}(k)\, dk \tag{134}$$

We set

$$C_t = \frac{1}{p^2 - E - i\sigma - (1-t^2)\Sigma} \tag{135}$$

Our Ward-type identity relies on the identity

$$\begin{aligned} 2k.k_{\beta'} &= (p+k)^2 - p^2 - 2k.(p-k_{\beta'}) - k^2 \qquad (136) \\ &= C_t(p+k)^{-1} - C_t(p)^{-1} - 2k.(p-k_{\beta'}) - k^2 \\ &\qquad -(1-t^2)\left[\Sigma(p+k) - \Sigma(p)\right] \qquad (137) \end{aligned}$$

In momentum space, the tadpole insertion of $J_{\substack{\alpha\alpha' \\ \beta\beta'}}$ can be written

$$\mathcal{T}(k) = \mathrm{tr}\left[\eta_{\beta'}^{(-u)} e^{-ik\cdot} \eta_\beta (G-C)\right] = \int dp\, \eta_{\beta'}(p) e^{-ipu} \eta_\beta(p+k)(G-C)(p+k,p) \tag{138}$$

We insert equation (137) to get

$$\begin{aligned} (2k.k_{\beta'})\mathcal{T}(k) &= \mathrm{tr}\left[\eta_{\beta'}^{(-u)} e^{-ik\cdot} \eta_\beta C_t^{-1}(G-C)\right] - \mathrm{tr}\left[\eta_{\beta'}^{(-u)} e^{-ik\cdot} \eta_\beta (G-C) C_t^{-1}\right] \\ &\quad -2k.\mathrm{tr}\left[\eta_\beta (G-C) D_{\beta'}^{(-u)} e^{-ik.}\right] - k^2 \mathcal{T}(k) \\ &\quad +(1-t^2)\,\mathrm{tr}\left[\eta_\beta (G-C) \eta_{\beta'}^{(-u)} (\Sigma e^{-ik.} - e^{-ik\cdot}\Sigma)\right] \qquad (139) \\ D_{\beta'}(x,y) &= \int dp\, e^{ip(x-y)} (p-k_{\beta'}) \eta_{\beta'}(p) \qquad (140) \end{aligned}$$

Now, we use the resolvent identity

$$G = C_t - C_t \lambda V G = C_t - G \lambda V C_t \tag{141}$$

Since $C$ and $C_t$ commute, we get

$$\begin{aligned} (2k.k_{\beta'})\mathcal{T}(k) &= -\mathrm{tr}\left[\eta_{\beta'}^{(-u)} e^{-ik\cdot} \eta_\beta \lambda V G\right] + \mathrm{tr}\left[G \lambda V \eta_{\beta'}^{(-u)} e^{-ik\cdot} \eta_\beta\right] \\ &\quad -2k.\mathrm{tr}\left[\eta_\beta (G-C) D_{\beta'}^{(-u)} e^{-ik.}\right] - k^2 \mathcal{T}(k) \\ &\quad +(1-t^2)\,\mathrm{tr}\left[\eta_\beta (G-C) \eta_{\beta'}^{(-u)} (\Sigma e^{-ik.} - e^{-ik\cdot}\Sigma)\right] \qquad (142) \end{aligned}$$

We put (142) back into the expression of $J_5$, writing

$$J_5 = -J_R + J_L - J_D - J_{k^2} + J_\Sigma \tag{143}$$

where the notations refer directly to the various terms of equation (142).

**Lemma 10**

$$\begin{aligned}
\|J_D\| &\leqslant O(1)(\log \lambda^{-1})\lambda^{1-r-2\nu_2-\varepsilon}\left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} && (144)\\
\|J_{k^2}\| &\leqslant O(1)(\log \lambda^{-1})\lambda^{2-2r-4\nu_2-\varepsilon}\left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} && (145)\\
\|J_\Sigma\| &\leqslant O(1)(\log \lambda^{-1})\lambda^{2-r-2\nu_2-\varepsilon}\left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} && (146)
\end{aligned}$$

**Proof**

We can treat $J_D$, $J_{k^2}$ and $J_\Sigma$ the way we treated $J_4$ because we have earned small factors:

- for $J_D$, we earn something thanks to

  $$k.D_{\beta'} \sim |k| M^{-j_0/2}\eta_{\beta'} \sim M^{-(1-r)j_0/2}M^{-j_2} \tag{147}$$

  but we have still the spatial integration of the tadpole to pay, which costs

  $$\int dx \left| \widehat{\left(\frac{\theta_{\beta'}}{2k.k_{\beta'}}\right)}(x) \right| \leqslant O(1)(\log \lambda^{-1})\lambda^{-2-\varepsilon} \tag{148}$$

  This is because we have

  $$\begin{aligned}
  \left\| \widehat{\frac{\theta_{\beta'}}{2k.k_{\beta'}}} \right\|_\infty &\leqslant O(1)M^{r\frac{j_0}{2}}M^{-j_2}\int_{\lambda^{2+\nu_3}}^{M^{r\frac{j_0}{2}}M^{-j_2}} \frac{dk_{/\!/}}{2|k_{\beta'}|k_{/\!/}} && (149)\\
  &\leqslant O(1)M^{r\frac{j_0}{2}}M^{-j_2}\log \lambda^{-1}, && (150)
  \end{aligned}$$

  and the spatial integration is in a volume $O(1)M^{-r\frac{j_0}{2}}M^{+j_2} \times \lambda^{-2-\varepsilon}$.

  Therefore

  $$\|J_D\| \leqslant O(1)(\log \lambda^{-1})\lambda^{1-r-2\nu_2}\left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \tag{151}$$

- for $J_{k^2}$, we earn something from

  $$|k^2| \leqslant M^{rj_0} M^{-2j_2} \tag{152}$$

  and the spatial integration of the tadpole has the same price as before.

  $$\|J_D\| \leqslant O(1)(\log \lambda^{-1}) \lambda^{2-2r-4\nu_2-\varepsilon} \left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \tag{153}$$

- finally, for $J_\Sigma$, we notice that $\Sigma$ is an almost local operator whose norm is proportional to $\lambda^2$. Thus, taking the commutator with $e^{-ik\cdot}$ gives a gradient term which is very small

  $$\|[\Sigma, e^{-ik\cdot}]\| \leqslant O(1) \lambda^2 |k| \tag{154}$$

  We can conclude

  $$\|J_\Sigma\| \leqslant O(1)(\log \lambda^{-1}) \lambda^{2-r-2\nu_2-\varepsilon} \left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \tag{155}$$

■

We are left with $-J_R + J_L$

$$\begin{aligned} -J_R &= -\lambda^2 \sum_{\alpha \not\sim \beta, \bar{\beta}} \sum_{\substack{\alpha' \simeq \alpha \\ \beta' \simeq \beta}} \int \xi(u)\, du \int \frac{\theta_{\beta'}(k)}{2k.k_{\beta'}}\, dk \\ &\quad \left\langle \operatorname{tr}\left[\eta_{\beta'}^{(-u)} e^{-ik\cdot} \eta_\beta \lambda V G\right] G \eta_\alpha e^{ik\cdot} \eta_{\alpha'}^{(u)} \right\rangle \qquad (156) \\ J_L &= \lambda^2 \sum_{\alpha \not\sim \beta, \bar{\beta}} \sum_{\substack{\alpha' \simeq \alpha \\ \beta' \simeq \beta}} \int \xi(u)\, du \int \frac{\theta_{\beta'}(k)}{2k.k_{\beta'}}\, dk \\ &\quad \left\langle \operatorname{tr}\left[G \lambda V \eta_{\beta'}^{(-u)} e^{-ik\cdot} \eta_\beta\right] G \eta_\alpha e^{ik\cdot} \eta_{\alpha'}^{(u)} \right\rangle \qquad (157) \end{aligned}$$

At this point, we use a diagrammatic representation to perform the connection with the heuristic presentation of section 4. It is easy to see that we have

$J_R =$  and $J_L =$  (158)

We take the degenerate part of the $V$ away

$$\eta_\beta V = \sum_{\gamma \sim \beta, \bar{\beta}} \eta_\beta V \eta_\gamma + \sum_{\gamma \not\sim \beta, \bar{\beta}} \eta_\beta V \eta_\gamma \tag{159}$$

so that we can write

$$J_{R,L} = J^{(0)}_{R,L} + J^{(1)}_{R,L}. \tag{160}$$

$J^{(0)}_{R,L}$ is the almost diagonal $V$ part, it has a bound

$$\|J^{(0)}_{R,L}\| \leqslant O(1)(\log\lambda^{-1})\lambda^{\frac{r}{2}-\varepsilon}\left(\frac{\lambda^2}{\sigma}\right)^2 \times \frac{1}{\sigma} \tag{161}$$

We integrate the $V$ by parts in $J^{(1)}_{R,L}$, and we use sector conservation and unfolding to generate the 12 terms of equation (36).

**Lemma 11** *There exists $\nu > 0$ such that*

$$\|J^{(1)}_{R,L}\| \leqslant O(1)(\log\lambda^{-1})^3\lambda^{\nu}\left(\frac{\lambda^2}{\sigma}\right)^3 \times \frac{1}{\sigma} \tag{162}$$

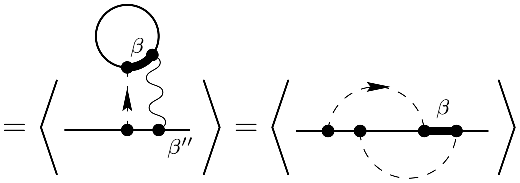
*where*

$$\begin{aligned}\nu &= \min\{(2-r-4\nu_1-2\nu_2), (\nu_2+\frac{r}{2}-\varepsilon),\\ &\qquad (1-r-2\nu_2-\nu_3-\varepsilon), 2(\nu_1-\nu_2-r)-\varepsilon\}\end{aligned} \tag{163}$$

**Proof**

Let us bound the various terms of (36). First, we consider the graphs without loops. We explain the bound for a typical one

$\mathcal{A}_1 =$



(164)

One can check that the analytic expression for $\mathcal{A}_1$ is

$$\begin{aligned}\mathcal{A}_1 &= \lambda^4 \sum_{\substack{\alpha\not\simeq\beta,\bar\beta\\ \gamma\not\simeq\beta,\bar\beta}} \sum_{\substack{\alpha'\simeq\alpha\\ \beta'\simeq\beta}} \sum_{\substack{\beta''\simeq\beta\\ \gamma'\simeq\gamma}} \int \xi(u)\xi(v)\,du\,dv \int \frac{\theta_{\beta'}(k)}{2k.k_{\beta'}}\zeta_0(k')\,dk\,dk'\\ &\qquad \left\langle G\eta_\alpha e^{ik\cdot}\eta^{(u)}_{\alpha'} G\eta^{(-v)}_{\gamma'} e^{ik'\cdot}\eta_\gamma G\eta^{(-u)}_{\beta'} e^{-ik\cdot}\eta_\beta e^{-ik'}\eta^{(v)}_{\beta''} G\right\rangle\end{aligned} \tag{165}$$

We bound $\mathcal{A}_1$ the way we bounded $I_1$ in lemma 8.

- Our small factors are $\lambda^4$ and the integration on $k$ and $k'$, *i.e.* $(\log\lambda^{-1})M^{rj_0/2}M^{-j_2}$ and $M^{rj_0}M^{-2j_1}$.

- We must get rid of the constraints on $\alpha$, $\beta$ and $\gamma$. This is done by introducing Gaussian random vectors and costs $(M^{(1-r)j_0/2}\log\lambda^{-1})^2$. Finally we must pay for the resolvents.

Gathering all factors, we get

$$\|\mathcal{A}_1\| \leqslant O(1)(\log\lambda^{-1})^3\lambda^{2-r-4\nu_1-2\nu_2}\left(\frac{\lambda^2}{\sigma}\right)^3 \times \frac{1}{\sigma} \tag{166}$$

Now, let us see how we can pair the graphs with loops to get a small result. For instance let us consider

$\mathcal{A}_2 =$ 
(167)

We know that the momentum $k$ at the first vertex is bounded by $K_1 M^{rj_0/2}M^{-j_2}$. Therefore, we can find $K_2$ such that if the momentum $k'$ at the second vertex is larger than $K_2 M^{rj_0}M^{-j_2}$ in norm, we have a leg higher than $2K_1 M^{rj_0/2}$. This leads to the decomposition

$$\mathcal{A}_2 = \mathcal{A}_2^{\text{high}} + \mathcal{A}_2^{\text{low}} \tag{168}$$

In $\mathcal{A}_2^{\text{high}}$, we have a high leg at the second vertex. But this leg can be $\eta_\beta$ (the thick line) and this would prevent us from making a staiway expansion and getting a small factor. Yet, in that case, we would know that at the first vertex, $\eta_{\beta'}$ (resp. $\eta_{\beta''}$) had to be higher than $K_1 M^{rj_0/2}M^{-j_2}$. Therefore, in the same way we did in lemma 10 we can show

$$\|\mathcal{A}_2^{\text{high}}\| \leqslant O(1)(\log\lambda^{-1})\lambda^{\nu_2+r/2-\varepsilon}\left(\frac{\lambda^2}{\sigma}\right)^3 \times \frac{1}{\sigma} \tag{169}$$

For $\mathcal{A}_2^{\text{low}}$, we use the fact that the first graph is equal to the second up to error terms.

- We change $\frac{\theta_{\beta'}(k)}{2k.k_{\beta'}}$ into $\frac{\theta_\beta(k)}{2k.k_\beta}$. The remainder term bears a factor

$$|k.(k_\beta - k_{\beta'})|\lambda^{-2-\nu_3} \leqslant O(1)\lambda^{1-r-2\nu_2-\nu_3} \tag{170}$$

- We exchange the ends of the two dashed lines in the middle loop. This amounts to commute first $e^{-ik\cdot}$ and $\eta_\beta$ and then $e^{-ik'\cdot}$ and $\eta_\beta$. Thus the error term has an extra factor

$$\max(|k|,|k'|)M^{j_1} \leqslant O(1)M^{rj_0}M^{-j_2}M^{j_1} \leqslant O(1)\lambda^{2(\nu_1-\nu_2-r)} \tag{171}$$

In conclusion, we obtain

$$\|\mathcal{A}_2^{\mathrm{low}}\| \leqslant O(1)(\log\lambda^{-1})\max[\lambda^{1-r-2\nu_2-\nu_3-\varepsilon},\lambda^{2(\nu_1-\nu_2-r)-\varepsilon}]\left(\frac{\lambda^2}{\sigma}\right)^3\times\frac{1}{\sigma} \qquad (172)$$

■

Taking $\nu_1$ small (but not too small) and $r$, $\nu_2$ and $\nu_3$ very small, the various powers of $\lambda$ (standing for the small factors we earned) that we met all along the demonstration are indeed positive. This concludes the proof of theorem 1.
